Bookstore Sales & Inventory Analysis

SQL Portfolio Project • PostgreSQL

Project objective

Use SQL to answer practical business questions about book pricing, orders, customer spending, sales by genre and author, and estimated inventory.

Dataset structure

Table	Purpose
Books	Title, author, genre, published year, price, stock
Customers	Customer name and location
Orders	Order date, customer/book IDs, quantity, total amount

Business questions explored

• Top 3 most expensive Fantasy books

• Average price of Fantasy books

• Total quantities ordered by genre and author

• Most ordered book

• Customers with at least two orders

• Cities where customers' combined spending exceeds $30

• Highest-spending customer

• Estimated remaining stock after orders

• Recorded revenue and basic data-quality checks

Skills demonstrated

SELECT, filtering, ILIKE, JOIN, aggregate functions (SUM, COUNT, AVG), GROUP BY, HAVING, ORDER BY, COALESCE, and date filtering.

Current status and limitations

Important: The provided SQL file includes table definitions and queries, but no actual inserted dataset. Numerical findings must be added after running the queries against the data. This report intentionally does not invent results.

Inventory assumption: the stock calculation is valid only if Books.stock is the starting stock and all order quantities represent fulfilled orders. If stock is already the current inventory, do not subtract orders again.

Next steps

1. Load the actual data into PostgreSQL.
2. Run each query and save result screenshots or CSVs.
3. Add 3–5 findings supported by real numbers.
4. Publish the SQL file and report on LinkedIn/GitHub, clearly describing this as a practice project.

Prepared as a beginner portfolio project template
